pro tip: any economic term with "real" = adjusted for inflation.

1 Intro to Economics

Corresponds to Chapter 2: "The Discipline of Economics."

1.1 What is Economics?

Definition 1 (Economics). The study of resources and how to optimally use resources. Often to answer the question "Should we do A or B with this limited resource?"

In this context, the word "resource" has a specific meaning.

Definition 2 (Resource). Anything that can be used to produce a good or service. Every resource is classified into one of three categories:

- **Land:** natural resources. (Eg. crude oil, farmland, oceans)
- **Labor:** work people do to produce goods and services. (Eg. physical labor like building or sports, mental labor like professors)
- **Capital:** equipment used to produce goods or more resources. (Eg. factories, computers)

Economics is broken into two fields: **microeconomics** and **macroeconomics**.

Definition 3 (Microeconomics). The study of economic problems faced at the individual level; individuals, families, and firms. Eg. "does this particular family save enough to provide for its future needs?"

Definition 4 (Macroeconomics). The study of economics problems faced at the national level; states, countries, and internationally. Eg. "should we allocate resources from national defense to education?"

Sometimes, we may discuss **positive economics**: the scientific analysis of economics via the hypothesis-test-conclusion model. Alternatively, we may discuss **normative economics**: the ethical analysis of economics- the way things *should* be.

1.2 Opportunity Cost and the PPF

Definition 5 (Opportunity Cost). The potential benefit lost from choosing one alternative over the other. For example, when you spend two hours studying, you lose two hours of relaxation. Gains of the option not chosen - gains of the opportunity chosen = opportunity cost.

In macroeconomics, opportunity cost is often quantative. If a nation decides to spend more resources to produce a good A, they will "lose" the good B that could have been produced with the same resources.

Figure 1: A Production Possibilities Frontier (PPF) showing a hypothetical nation's possible production of bikes and cars.

For example, consider Figure 1. In this case:

$$\text{Opportunity Cost of Bikes} = \frac{\text{Change in Car Production}}{\text{Change in Bike Production}} = 0.5\text{cars/bike}$$

The opportunity cost of cars is the reciprocal of the opportunity cost of bikes: that is, 2 bikes/car.

Figure 1 is a **production possibilities frontier**: it shows all the combinations of the goods that can be produced if the economy uses all of its

resources fully and **efficiently** (to their maximum potential). *All points on the curve are optimal; a normative analysis is required to determine what point is preferred.*

Points "inside" the PPF are possible, but aren't optimal. (This may occur due to environmental, labor or other restrictions.) Points "outside" the PPF are currently impossible: resources can't be used efficiently enough to reach that point.

The PPF may shift for two primary reasons: changes in the *amount of resources* or *productivity/technology*. Increasing the amount of resources or improving technology used to produce said resources would shift the PPF to the right. Similarly, decreasing the amount of resources or somehow regressing in technology (war/disaster) would shift the PPF to the left.

1.3 Laws of Costs

Often, PPFs aren't straight lines; the opportunity cost varies depending on the current amount being produced. More often, the opportunity cost of each extra product increases per product already produced. Graphically, this causes a PPF concave to the origin. This is known as **the law of increasing costs**.

Generally, the law of increasing costs happens as people less and less in tune with producing a good are hired to produce it.

Alternatively, the inverse may happen: the opportunity cost of each extra product may decrease per product already produced. This may happen as more infrastructure is put into place, it takes less resources to produce each unit good. This causes a PPF convex to the origin, and is known as **the law of decreasing costs**.

1.4 Absolute and Comparative Advantage

Definition 6 (Specialization). When an entity focuses on the production of a limited scope of goods for greater efficiency.

It can be shown that dividing labor into specialized tasks could increase productivity and output, *even at the national scale*.

Consider Figure 2. In this case, China has the **absolute advantage** in both food and cloth because China can produce both more efficiently than Argentina. However, Argentina has the **comparative advantage** in cloth, because it has a lower opportunity cost (0.25 food/cloth vs. 2 food/cloth). Similarly, China has the comparative advantage in food (0.5 cloth/food vs. 4 cloth/food). It can be shown that by specializing in the good a nation has

Production per unit of Labor:		
	China	Argentina
Food	200	20
Cloth	100	80

Figure 2: A hypothetical example of production costs of food and cloth in China and Argentina.

a competitive advantage of, the maximal amount of goods will be produced between the two nations.

Supposing that countries only produce their competitive advantage good, an optimal trading ratio to benefit both countries can be found by considering opportunity cost. Trading x units of food for y units of cloth would be optimal if x/y is less than the opportunity cost of cloth in China (2 food/cloth) and y/x is less than the opportunity cost of food in Argentina (4 food/cloth). For example, trading 1 unit of food per 1 unit of cloth would benefit both countries, as it is less than both of the countries' individual opportunity costs.

2 Economic Systems

Corresponds to Chapter 3: "Economic Systems."

Economics deals with three primary problems:

- How much, if any, of each good and service should be produced?
- Who will get how much of each good and service?
- How should these goods and services be distributed?

While these problems may be easy to answer for small systems, these problems become exponentially harder to deal with as the size of the economy grows. Note the idea of opportunity cost (producing something will reduce production of other products) and *related costs*: producing more of a product will require more production of capital.

For example, producing more food may take away money from the cosmetic industry; opportunity cost; and require the production of more tractors and farm equipment; related costs.

Societies tackle this problem in three ways: **command economies**, **capitalism**, or a mix of the two. These can be viewed as a spectrum: command economies on one end, and capitalism on the other.

2.1 Command Economies

Definition 7 (Command Economy). Also referred to as "communism" or "socialism." An economy in which the government determines what will be produced, how much will be produced, and who receives the products.

Command economies use quotas and production plans to dictate how much of each good or resource is produced. By setting prices on goods and services and controlling the wage rates of almost all citizens, the government is able to control the access to products.

Due to how interconnected individual goods and services are with one another, it is nearly impossible to perfectly coordinate production requirements. Many quotas may fail if a "requirement" quota fails to be met. Additionally, incentives to work hard and innovate are discouraged, as there is little benefit for doing so.

However, command economies can also artificially change prices; ex. artificially lowering the price of textbooks to encourage education. Additionally, fixed wages can eliminate the lower class.

Two examples of countries with command economies are Cuba and North Korea.

2.2 Capitalism

Definition 8 (Capitalism). Economic system where supply and demand determine prices.

In a capitalist economy, the **consumer** dictates the production of goods. For example, if consumers want more of a certain product, the purchases of that product will go up. This signals to producers to increase the production of that product (often cutting something else in the process).

An individual's income determines how much of the net production they will receive. Income is also another variable within such an economy (the price of labor).

In a purely capitalist economy, the government has no direct influence. However, in practice, no country is purely capitalist: the government often needs to step in when the economy won't equitably provide important resources, like food or higher education.

2.2.1 Allocative Efficiency

Definition 9 (Allocative Efficiency, the "invisible hand"). When resources are deployed to produce just the right amount of products to satisfy society's wants.

When prices are determined by a capitalist economy, **allocative efficiency** is achieved. The capitalist economy is able to answer the critical questions of economics in a *decentralized* way (with no ruling body). Products and quantity are determined by the consumer, as mentioned before. Who receives goods is also answered, as the price of labor will reward those who appeal to consumer wants.

2.3 The Circular Flow Diagram

In capitalist economies, most of the resources are "owned" by individuals and households; via stockholders "owning" companies and government facilities being "owned" by everybody.

Definition 10 (Market). A mechanism that allows buyers and sellers to exchange a good or service.

The **circular flow diagram** (3) shows how resources are flow from households to firms in exchange for wages. This trade of resources for money is known as the *market for resources* or *factor market*. Households spend their income to purchase goods and services supplied by firms: the *market for goods and services* or *product market*.

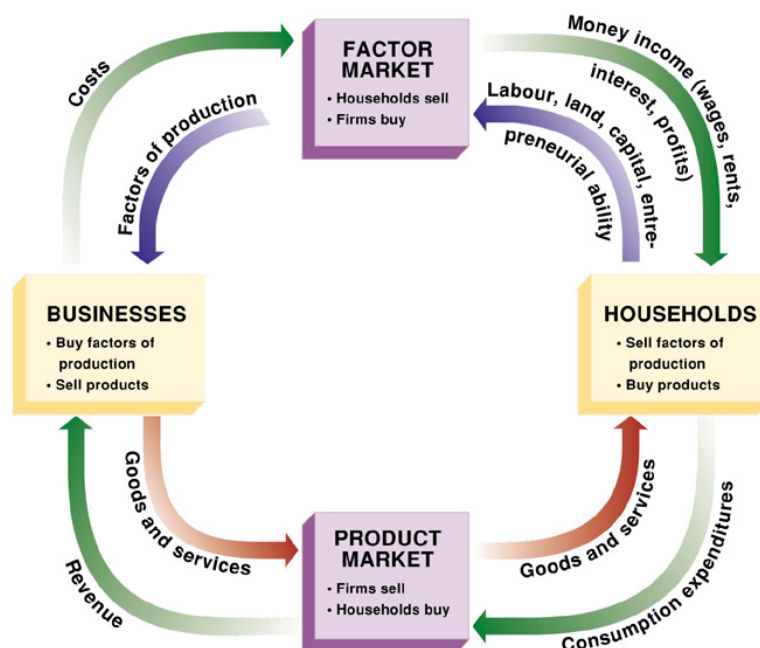

Figure 3: The Circular Flow Diagram.

3 Supply and Demand

Corresponds to Chapter 4: "Demand and Supply: The Basics."

3.1 Demand

Definition 11 (Demand). The quantity of a product a consumer is willing and able to purchase at each and every prices. The demand for a product is shown graphically as a demand curve.

Definition 12 (Law of Demand). Holding all else equal (*ceteris paribus*), if the price of a product increases, the quantity demanded decreases and vice versa. Equivalently, the slope of a demand curve is always negative.

There are three major reasons for why the Law of Demand happens:

1. **The Income Effect:** When prices fall, consumers can afford to buy more of a product, and vice versa. The *purchasing* power of the consumer decreases as the prices increase.
2. **The Substitution Effect:** If a substitute for a good exists, an increase in price for the good will lead to more demand for the alternative and thus less demand for the original good.

3. **Diminishing Marginal Utility:** As more units of a product are "consumed" the *utility* or satisfaction from each individual product decreases. As utility decreases, so does the price the consumer is willing to pay.

Figure 4: Demand curves.

3.1.1 Changes in Demand and Quantity Demanded

Definition 13 (Quantity Demanded). The quantity of a product demanded at **one** specific price. When **only the price** of a product changes, the quantity demanded will change. This is the movement of a point along a **constant** demand curve.

An increase in demand leads to a shift to the right, VV.

On the other hand, if the **determinants of demand** change, then the demand curve *will* shift the curve to the left or right. The determinants of demand are as follows:

Substitute Goods are two goods that are interchangeable- see the substitution effect. When the price of the original good goes up, the quantity demanded for the original good decreases and the demand *curve* of the substitute good will go outwards, thus resulting in a shifted quantity demanded.

Preferences refer to consumers' tastes or preferences for a good or service. If people's desire for a product increase, then the demand curve will shift to the right, and vice versa.

Population refers to the total number of buyers in a specific market. Bigger market = more demand = shift to the right.

If a consumer's **income** increases, their demand for all products will generally increase. Most goods are *normal goods* (income increases = demand for good increases), but some may be *inferior goods* (income increases = less demand). Think of normal goods like superior products (new car, new clothes) and inferior goods like poor products (used cars, second-hand clothes).

Complementary Goods are goods that are purchased separately but used together. When the demand for the original good goes up, so will the demand for the complementary good, and vice versa. Like the opposite of substitute goods.

Expectations of higher prices will increase the current demand before the price increases.

Remember the acronym SPICE:

- **S**ubstitute Goods
- **P**references and **P**opulation
- **I**ncome
- **C**omplementary goods
- **E**xpectations

3.2 Supply

Similar to consumers, suppliers also have their own **supply** curves.

Definition 14 (Supply). The quantity of product a supplier is willing and able to produce or put on sale at each and every price. The supply for a product is shown graphically as a supply curve.

Definition 15 (Law of Supply). *Ceteris paribus*, if the price of a product increases, the quantity of product a supplier is willing to provide increases. Equivalently, the slope of a supply curve is always positive.

The Law of Supply happens for two major reasons:

1. Greater price = more profit. yeah thats it
2. As producers increase production, the marginal cost of producing each product increases, requiring higher prices to justify producing a higher quantity of product.

3.2.1 Changes in Supply and Quantity Supplied

Definition 16 (Quantity Supplied). The quantity of a product produced at **one** specific price. When **only the price** of a product changes the quantity produced will change. This is the movement of a point along a **constant** supply curve.

Yet again, there exist **determinants of supply**. Note, in this case, an increase in supply would lead to a *shift to the right*- more quantity for less price. VV. The determinants of supply are as follows:

Resource costs and availability: when the cost of producing a product increases, the supply of that product will decrease, VV. When one of the resources (land, labor, capital) used in production changes in price, supply will change.

Alternative Prices: sometimes, a firm can easily switch between several different products. In some cases, it may be better to produce more of another product to maximize profit. Thus, the prices of alternative prices will affect the supply of both.

New **technology** can decrease production costs and increase productivity, resulting in greater supply.

Taxes on the production of a good will result in increased production costs, decreasing supply. Alternatively, a **subsidy**- payment from the government to produce a product- will increase profits at all levels and increase supply.

Similar to consumers, if producers **expect** higher prices in the future, they may hold back the amount produced, decreasing current supply for the ultimate goal of increasing profits in the future. VV.

A greater **number of sellers** increases net supply. While the extra competition may decrease the supply for an individual seller, the result is a greater supply overall. This is usually good for consumers, who receive more choice and lower prices as the supply curve shifts to the right.

Remember the acronym ROTTEN:

- **R**esource costs and Availability
- **O**ther good's prices
- **T**hcome
- **T**axes and Subsidies
- **E**xpectations
- **N**umber of sellers

3.3 Market Equilibrium

At the point where the supply and demand curve intersects, there exists **market equilibrium**: consumers want the exact amount that producers want to produce. This is also known as the *market-clearing price*. Otherwise, there is **disequilibrium**: the market is sub-optimal for consumers and producers.

A **surplus** exists if supply outweighs demand, resulting in lower prices and thus lower supply. A **shortage** exists if demand outweighs supply, resulting in higher prices and thus higher supply. In a perfectly competitive market, both scenarios will eventually converge back to equilibrium.

3.3.1 Changes in Equilibrium

Questions may ask about an equilibrium price after a supply and/or demand shift.

To solve these, first consider what curve the shift is affecting: supply, demand, or both? Then, consider whether it is an increase (right) or decrease (left), and then shift the curve, noting the new equilibrium. Generally, shifts should follow the following table. If in doubt, draw a picture of supply and demand.

Change	Shift	Eq. Price	Eq. Quantity
Supply Increase	Supply Right	Down	Up
Supply Decrease	Supply Left	Up	Down
Demand Increase	Demand Right	Up	Up
Demand Decrease	Demand Left	Down	Down

Figure 5: Table of both supply and demand shifts and effects.

3.3.2 Double-Shifts

Occasionally, questions may be asked where there are simultaneous shifts in both demand and supply. **For the purposes of AP Macroeconomics, you will NOT need to calculate exact double-shift equilibrium values.** Therefore, some values will be indeterminate- see the table below.

Demand	Supply	Eq. Price	Eq. Quantity
Increase	Increase	Indeterminate	Increase
Decrease	Decrease	Indeterminate	Decrease
Increase	Decrease	Increase	Indeterminate
Decrease	Increase	Decrease	Indeterminate

Figure 6: Table of simultaneous supply and demand shifts and effects on equilibrium.

4 Gross Domestic Product

Corresponds to Chapter 12: "The National Economic Accounts."

4.1 What is GDP?

Definition 17 (Gross Domestic Product (GDP)). A measure of the dollar value of production within a nation's borders annually. Generally speaking, bigger GDP = healthier economy. For 2021, USA's GDP was estimated around \$23.0 trillion.

Broadly speaking, GDP can be calculated as follows:

1. A representative surveys the major suppliers and retailers of a product.
2. Through this survey, an estimate for the total number of products produced and their average value is obtained.
3. Number of products produced \times average product price \approx GDP for that specific product.
4. Total GDP = \sum GDP for all products

In step (3), only considering the total number of products *sold* yields the *final sales* metric. This is **NOT** the GDP.

4.2 Estimation Techniques

In practice, there are many complications with the process discussed above. Different estimation techniques account for these complications, but often introduce their own flaws. In theory, all estimates should have the same value, but this is often not the case.

4.2.1 Expenditures

Rather than considering individual products, the **expenditure** approach breaks down GDP into several expenditure categories, which are calculated individually and summed together.

- **Consumption Expenditures** refer to all the goods and services produced and sold to households.
- **Government Expenditures** refer to all goods and services produced and sold to local, state, and federal governments. Governments often buy products that households will not (eg. fighter jets) or products in quantities that differ from households (eg. high-end computers)
- **Investment Expenditures** (sometimes just "investment") refer to all capital goods and services, including plants, equipments, residential construction, and final sales (see section 4.1). This category mainly consists of independent companies/firms.
- **Exports and Imports:** many goods may be produced here and sold abroad, or goods may be purchased from abroad. As imports are produced outside a country's borders (not part of GDP), imports are subtracted from exports to get *net exports*.

The expenditure approach to GDP is summarized with the following formula:

$$\text{GDP} = C + I + G + X$$

where C = consumption expenditures (by households), I = investment expenditures (by firms), G = government expenditures, and X = "net exports" = exports - imports. Often, a majority of GDP comes from consumption expenditures (70% in 2021).

While this formula appears simple, note that calculating even one of these variables requires significant effort and time.

4.2.2 Income

The revenue gained by producing a product is distributed between the different producers of that product: often including labor, materials, overhead (utility companies), and the producer company. Obviously, the revenue gained by all parties would be just enough to buy that product back. Therefore, in theory, GDP can be calculated by considering **the total income of the economy** instead- the **income approach**.

Wages and salaries are the predominant type of income. Other types of income include:

- Proprietors' income: income earned by self-employment or unincorporated businesses (???)
- Rental income: income from the use of occupation or porperty (renting stuff)
- Interest income: income from bank interest lmao
- Corporate profits: income gained by companies that are distributed to its shareholders

Some adjustments need to be made once the total is summed- notably, indirect buisness taxes (ex. buisness licenses), depreciation, and other mis-callenous items must be accounted for.

4.2.3 Value-Added

The **value-added approach** considers what producers and industries add "value" to the final retail price.

Consider a producer gathering raw uranium, enriching it, and selling it to a nuclear reactor for (hypothetical) \$10. The nuclear reactor uses this refined uranium to generate power, which is sold to customers for (hypothetical) \$15, adding \$5 of value in the process. The GDP in this scenario is calculated by adding the value of the uranium at each stage of the process: \$0 (raw uranium) + \$10 (refined uranium) + \$5 (power).

While the U.S. does not use the value-added approach in the BEA (see National Accounts), other countries often use this approach to estimate GDP and set taxes at each stage of production.

4.2.4 Real GDP

GDP itself **DOES NOT** account for price changes. Simply because this year's GDP was greater than last year's GDP does NOT imply that we produced more this year: prices could have simply risen higher than last year.

To account for this, **real GDP** (or "constant-dollar") is calculated using the prices from a **base year**. It doesn't matter which year is chosen as the base; it ensures that all prices are held constant, such that any changes are due to a change in production alone. (To differentiate, regular GDP may be referred to as "nominal" or "current-dollar" GDP.)

4.3 Other GDP Factors

4.3.1 The Underground Economy

The underground economy refers to goods and services not counted in GDP- anything that does not pass through a market. This obviously includes illegal activity (drugs, bribes, etc...), but also undocumented activities, notably any activities that households do for themselves.

This accounts for a significant amount of GDP, and some sources say that it can account for more than 50% of GDP.

4.3.2 Per Capita GDP

While Japan and Montana are the same size, they have vastly different GDP's. This is mainly due to population- the population of Japan is about 128 times that of Montana.

To compare which has a "higher standard of material well-being," divide the GDP by the population to get the **Per Capita GDP**.

4.3.3 Limitations of GDP

GDP is used as the primary measure of a country's quality of life. However, it's not perfect: GDP does not account for social factors (war, class inequality, traffic, etc...) or where products go (possibly to a few select families).

4.4 National Economic Accounts

The **National Economic Accounts (NEA)** make up a comprehensive group of statistics that measure various aspects of the economy's performance. Notably, the NEA tracks many measures of income and production, including GDP. The NEA provides estimates for the USA's GDP using all the estimation techniques discussed above, providing relevant substatistics. Updates are published under a periodical titled "Survey of Current Business," and are available online at the home page of the *Bureau of Economic Analysis* (BEA), an agency within the Department of Commerce.

The BEA provides "flash" updates for GDP each quarter, about 30 days after the quarter ends. Annual estimates of GDP are much more reliable, but they too are subject to revision.

5 Inflation and Unemployment

Corresponds to Chapter 13: "Inflation and Unemployment."

5.1 Inflation

Definition 18 (Inflation). A sustained increase in most prices in the economy.

Disinflation is when the inflation *rate* is decreasing (second derivative is negative). In disinflation, prices are still rising, just not as quickly.

Deflation is when there is a sustained decrease in most prices in the economy: the opposite of inflation.

5.1.1 The Consumer Price Index

Definition 19 (Consumer Price Index (CPI)). A measure of the average change over time of the prices paid by urban consumers for a set of several commonly purchased products and services ("basket of goods").

Like real GDP, CPI is calculated relative to a "base" year. The CPI at a specific time is calculated as (Total cost for the basket at that time) / (Total cost for the basket at the base time) * 100. The CPI for the base time is always 100. To calculate the **inflation rate** between two time periods, take the percentage change in the CPI.

For example, suppose that at the base year, households buy 5 cheese at \$2.00 each and 8 crackers at \$1.25 each. Total cost = $\sum n_i p_i = 5 \times \$2.00 + 8 \times \$1.25 = \20.00 . By definition, the CPI of this year is 100.

Now, suppose that the price of cheese rises to \$2.25 the next year. Now, the total cost is $\sum n_i p_i = 5 \times \$2.25 + 8 \times \$1.25 = \21.25 . The CPI for this year is $\frac{\$21.25}{\$20.00} \times 100 = 106.25$. So the inflation rate between this year and the base year would be $\frac{106.25 - 100}{100} = 0.0625 = 6.25\%$.

Like all measures, CPI is not a perfect measure of inflation. The CPI only considers **price changes**- it does not account for external factors, like quality of goods. For example, while the price of cars have increased significantly since the 1950s, the quality of cars have also gone up in parallel, increasing the CPI when it shouldn't. It can be shown that **the CPI overstates the amount of inflation present**- one study found it to overestimate inflation by > 1%. This discrepancy is important, as some programs like the Social Security program adjust crucial payments with the CPI.

The CPI is recalculated every month by the Bureau of Labor Statistics (BLS) based on 90,000 different items at 23,000 retail and service outlets in twenty metropolitan areas.

5.1.2 The GDP Deflator

As mentioned in section 4, we have two measures of GDP: real and nominal GDP. Comparing the two leads to another way to measure inflation: the **GDP deflator**.

$$\text{GDP Deflator} = \frac{\text{GDP}}{\text{Real GDP}} \times 100$$

Note that if we have GDP and the GDP deflator, we can calculate real GDP with the following rearrangement:

$$\text{Real GDP} = \frac{\text{GDP}}{\text{GDP Deflator}} \times 100$$

Like CPI, to calculate the inflation rate between two years, take the percentage change in GDP deflator.

The GDP deflator ignores import prices- if the price of imported cars increases, the CPI will increase but the GDP deflator will not. However, the CPI ignores price changes for non-consumer items: if costs for government items increase, then the GDP deflator will increase but the CPI will not. The inflation rates derived from the GDP deflator and the CPI have been different, but have not differed significantly for most years.

5.1.3 Costs of Inflation

Inflation erodes direct purchasing power. Households whose incomes do not match the pace of inflation are hurt, as they are able to purchase less with the same income. *However*, this does not affect most households, as their income often keeps pace with if not exceeds inflation. (This happens as extra revenue from high prices are either 1. passed back as higher wages or 2. gained as profit, which are then returned to stockholders as dividends. Thus, *inflation often increases class inequality*.)

Inflation erodes the purchasing power of savings. Even if a household's income matches inflation, the value of savings- savings accounts, trust funds, other forms of financial wealth- will be worth less than before the inflation. Thus, many households, businesses, and governments may be forced into taking loans.

Resources are wasted adjusting to higher prices. Brochures, restaurants, and price lists in the media have to be changed constantly to adjust for higher prices. Resources that are used adjusting to higher prices instead of something useful are known broadly as "menu costs."

The value of loans decrease. If the rate of interest does not match the rate of inflation, the loaner will lose purchasing power versus had they

kept the loan. This benefits borrowers, as they are able to repay lenders with inflated money.

Major lenders, like banks, protect themselves by charging higher interest on loans. This is codified in **Fisher's Hypothesis**: $\text{Nominal Interest Rate} = \text{Real Interest Rate} + \text{Expected Inflation (over the course of the loan)}$. As such, lenders who do *not* expect inflation are hurt.

One major lender that is hurt by inflation are households. Nominal interest paid by banks isn't adjusted for inflation, so households are hurt by inflation. The federal government is the biggest borrower in the U.S. economy. Thus, it stands to benefit from inflation the most, as it can repay loans with inflated dollars. In some sense, inflation is like a tax- wealth is redistributed from lenders to borrowers.

5.2 Unemployment

Definition 20 (Employment). An individual is *employed* if they are older than 16 and have done at least one of the following:

- Work for pay or profit for one or more hours
- Work without pay for 15 or more hours in a family business
- Have a job, but haven't worked due to time off

Definition 21 (Unemployment). An individual is *unemployed* if they are not employed BUT actively looking for employment.

Definition 22 (Labor Force). All those in an economy who are able to contribute labor. This includes all unemployed and employed people in an economy. Note that retirees, those too young to work, and anyone who is not actively seeking employment are not included in the labor force.

Definition 23 (Unemployment Rate). The number of unemployed individuals divided by the size of the labor force.

The Bureau of Labor Statistics reports unemployment statistics from two broad surveys each month, one contacting employers and the other contacting households.

5.2.1 Types of Unemployment

Discouraged Workers / Hidden Unemployed: those who are able to work, but not actively seeking employment because they are discouraged

about their prospective employment opportunities. These workers do not show up in the labor force as they are not actively seeking employment.

Structural Unemployment: those unemployed due to structural disadvantages. Eg. Welders may be looking for work in Cleveland, but all the secretary jobs are in Cleveland and all of the welding jobs are in Dallas. Very hard to remedy- having people relocate is no easy task.

Seasonally Unemployed: those only able to find work for a portion of the year due to the seasonal nature of their jobs. Considered to be seasonally unemployed as long as they actively look for work in the off-season.

Cyclical Unemployed: those unemployed due to economic slowdowns, typically recessions ("during the contractionary phase of the business cycle"). Hopefully, these people will be back to work when production picks up during the next expansion.

Frictionally Unemployed: those not working due to being "between" jobs. Eg. someone who does not have a job but is scheduled to begin one next month. Includes those who quit jobs to look for another and graduates entering the labor force.

5.2.2 Problems with the Unemployment Rate

- The unemployment rate doesn't account for hidden unemployment.
- Part-time employment is counted equally to full-time employment.
- The unemployment rate varies significantly across locations and demographics.
- Overall, the unemployment rate understates the unemployment problem.

Just because there is unemployment does not mean the economy is not perfectly efficient.

Definition 24 (Natural Rate of Unemployment). The amount of unemployment that exists when the economy is producing on its PPF, due to frictional and structural unemployment. If there is no cyclical employment, then the economy is producing on its PPF. Economists consider the economy to be at full employment when the employment rate falls into the 4-5% range, where there is little to no cyclical unemployment.

5.2.3 Costs of Unemployment

- Households will encounter hardship, maybe even hunger.
- Unemployment means that labor (a key resource) is not being used to its fullest potential- we are producing inside the PPF.
- Unemployment is especially a problem during recessions (when GDP is declining), as the amount of labor and other capital goods is decreased, leading to more unemployment.

6 Money and Banking

Corresponds to Chapter 14: "Money and Banking"

6.1 What is Money?

Definition 25 (Money). Anything that is generally accepted as a medium of exchange; payment for a good or service.

Definition 26 (Currency). Physical forms of money, notably including coins issued by the Treasury and paper money issued by the Federal Reserve.

Definition 27 (Demand Deposits). Also known as checkable deposits. Money held in checking accounts, which can be withdrawn at any time. Includes money held in savings accounts, loans, credit unions, and the like (*other checkable deposits*).

Note that deposits in savings accounts are considered as money, as it is easy to move money from a savings account into checking accounts or cash. Savings deposits are highly *liquid*- they can be turned into cash rapidly with little cost.

Although not officially currency, demand deposits practically function the same way, being accepted in many places.

6.1.1 M1 and M2

There are two major definitions of money, known as **M1** and **M2**.

The **M1 definition of money** is currency, demand deposits, and *other liquid deposits*: other checkable deposits + deposits in savings accounts.

The **M2 definition of money** is everything in M1 plus small deposits and retail money market funds. (definitions unnecessary for AP- just know they're less liquid than savings accounts)

Note that under both definitions, currency inside a bank is not considered part of currency in circulation. Deposits would be considered money under M1 and M2, but also as currency, therefore leading to double counting.

The majority of money consists of demand deposits and other liquid deposits.

For the rest of this text, "banks" will refer to all depository institutions.

7 Monetary Theory

Corresponds to Chapter 15: "Monetary Theory"

8 Aggregate Supply and Demand

Corresponds to Chapter 16: "Aggregate Supply and Aggregate Demand"

9 Monetary Policy
